Re: 2024 Annual Progress Report for Management of High-Risk Conditions at the 5100 Portal Area of the former Sunro Mine, Jordan River BC, Site ID 16790

This letter provides an annual update for the 5100 Portal Area of the former Sunro Mine ("Site"), as requested in the Ministry of Environment and Climate Change Strategy's (ENV) letter to Teck Resources Limited (Teck) and the former Western Forest Products Inc. (WFP), dated September 18, 2017. We note that WFP sold the property to Forebay Holdings Inc. (Forebay) in June 2021.

This annual report provides an update on studies completed from July 2023 to July 2024. The studies focused on water quality monitoring and terrestrial risk assessment of the South Waste Rock Pile.

Risk Assessment Objectives

Teck retained AtkinsRéalis Canada Inc. (formerly SNC-Lavalin Inc.) to conduct a preliminary terrestrial risk assessment (PTRA) for the South Waste Rock Pile. The purpose was to evaluate the potential for exposures and risks from metals identified in soil to people using this Site, as well as to terrestrial ecological receptors. The results of the PTRA will be used to support risk management and remediation decision-making for this area of the Site.

The PTRA is included in the attached report entitled *Preliminary Terrestrial Risk Assessment, South Waste Rock Pile and the Sunro Mine Site, Jordan River, BC, dated June 5, 2024* prepared by AtkinsRéalis. In summary, there were no contaminants of potential concern (COPCs) for human health identified in surface soil at the South Waste Rock Pile; therefore, no unacceptable risks to human health are estimated based on direct soil exposure. With respect to terrestrial risk estimates, based on current site biological observations and habitat assessment, the effects to terrestrial ecological receptors were deemed unlikely at the population or community level. However, the habitat assessment identified that there is potential for suitable habitat for the Northern Red-legged Frog (*Rana aurora*) and Wandering Salamander (*Aneides vagrans*). Both are Species at Risk (SAR) in accordance with Schedule 1 of the *Species at Risk Act* (Special Concern) and are on the blue list in British Columbia. Neither species was observed during the habitat assessment; however, an observance of the Northern Red-legged Frog was recorded approximately 1.4 km to the east and there is a potential for presence of the Wandering Salamander according to the BC Conservation Data Centre iMap tool.

In 2025, Teck will conduct a detailed mapping of habitat to confirm or determine the likelihood of presence for potentially SAR amphibians on site. The results of the amphibian survey will determine if a Detailed Ecological Risk Assessment may be required.

Based on the results of the PTRA, implementation of additional mitigation measures is unlikely necessary at this time to reduce risks for human and terrestrial receptors. Teck will re-evaluate this conclusion based on the results of the SAR amphibian survey and if a Detailed Ecological Risk Assessment determines otherwise.

Cover Performance Effectiveness Monitoring Program

Teck has retained AtkinsRéalis to conduct water quality sampling subsequent to the installation of the interim cover over the North Waste Rock Pile in fall 2021 to determine its effectiveness. The objectives of this program are to i) measure water quality in the Jordan River downstream of the cover and 5100 Portal to document changes, ii) build upon the existing dataset to assess trends and support future remedial efforts at the site, and iii) assess the impact the cover has had on overall metal concentrations in the surface water of the Jordan River, downstream of the 5100 Portal. Specifically, the sample locations were selected from the baseline dataset (pre-liner locations) to determine if the seasonal increases in metals concentrations observed in porewater have been mitigated.

To date, five effectiveness monitoring program sampling events have occurred between February 2022 – November 2023, with two more planned to be completed in August 2024 and November 2024. The interim results have been incorporated into the attached report entitled *Post Liner Installation Interim Water Quality Monitoring Results, Sunro Mine, dated July 10, 2024* prepared by AtkinsRéalis. In summary, the groundwater, porewater and surface water results were generally within historical results. Two exceptions are new maximum dissolved copper concentrations in the samples collected from groundwater MW18-04 (located within the tailings area) and porewater PW17-17 (the downstream location). Interpretation of these results has not been provided at this time.

Based on the interim results, there does not appear to be a significant loading of dissolved copper to the Jordan River as it flows past the North and South Waste Rock Piles. A detailed report will be prepared following the 2024 sampling events and will be submitted with the July 2025 annual report. The monitoring objectives will also be reviewed and the water quality program may be adjusted accordingly.

Subsequent to the completion of the 2024 monitoring program, Teck will use the data to inform the development of the next steps and timelines. During this time, Teck will continue to engage with the stakeholders on the results and will develop a plan for next steps for submission as part of the annual report due July 15, 2025.

We trust this letter update meets your current requirements. Please contact me if you have questions.

Sincerely,

Michelle Unger, B.Sc.
